Memory layout

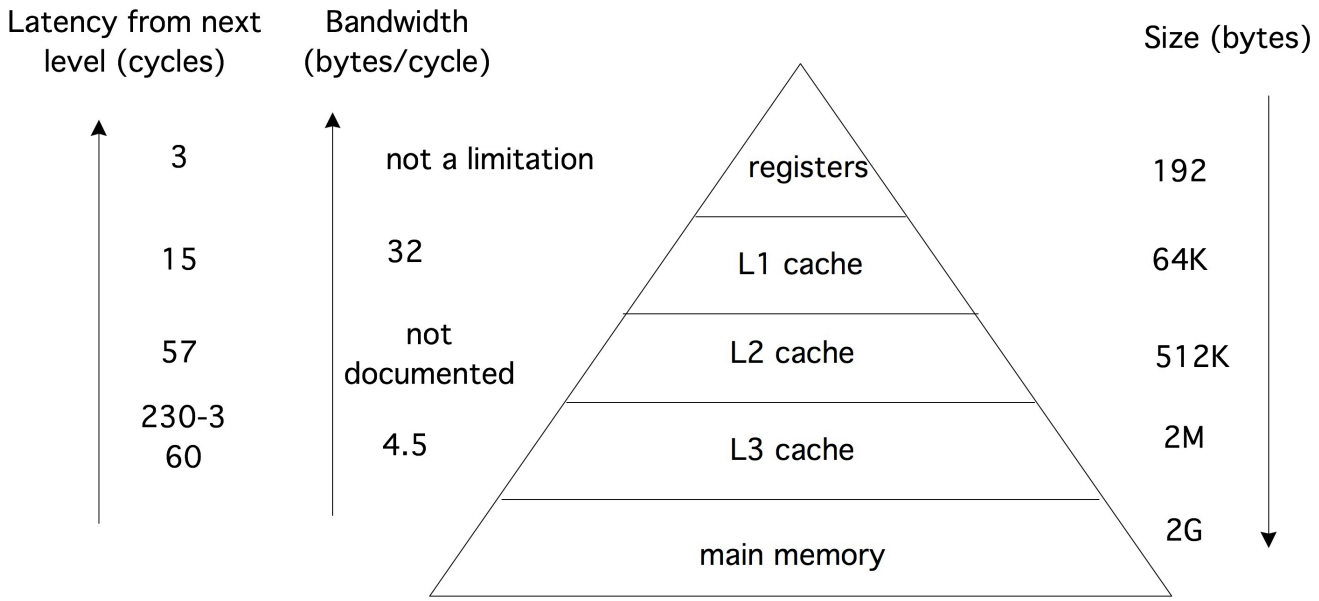
Try it on your laptop!

```
$ lstopo
```

Hierarchy



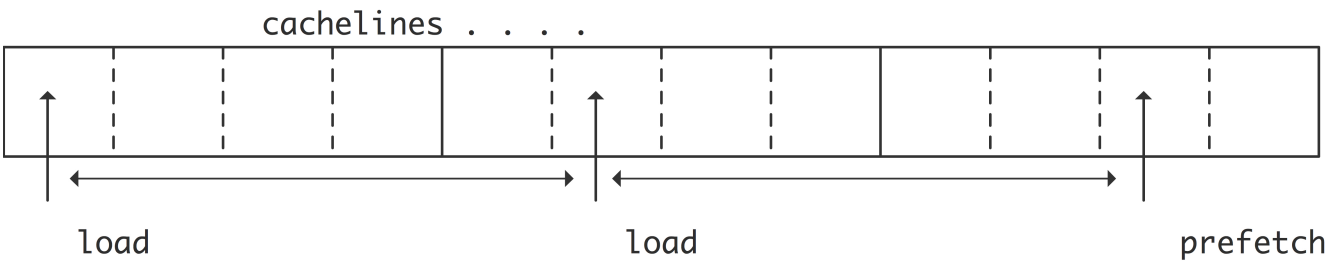
Latency of n bytes of data is given by

$$\alpha + \beta n$$

where α is the start up time and β is the inverse of the bandwidth.

[Eij10; Figure 1.5]

Cache lines and prefetch



- Accessing value not in the cache → *cache miss*
- This value is then loaded along with a whole cache line (e.g., 64 or 128 contiguous bytes)

- Following cache lines may also be anticipated and prefetched

This shows the importance of *data locality*. An algorithm performs better if it accesses data close in memory and in a predictable pattern.

[Eij10; Figure 1.11]

```

```julia
mat = rand(Cfloat, 2^8, 2^8)
```

```julia
c_sum(x::Matrix{Cfloat}) = ccall(("sum", sum_matrix_lib), Cfloat, (Ptr{Cfloat}, Cint, Cint), x, size(x, 1), size(x, 2));
```

```c
#include <stdio.h>

float sum(float *mat, int n, int m) {
  float total = 0;
  for (int i = 0; i < n; i++) {
    for (int j = 0; j < m; j++) {
      total += mat[i + j * n];
    }
  }
  return total;
}
```

▶ **What is the performance issue of this code ?**

Arithmetic intensity

Consider a program requiring `m` load / store operations with memory for `o` arithmetic operations.

- The *arithmetic intensity* is the ratio $a = o/m$.
- The arithmetic time is $t_{\text{arith}} = o/\text{frequency}$
- The data transfer time is $t_{\text{mem}} = m/\text{bandwidth} = o/(a \cdot \text{bandwidth})$

As arithmetic operations and data transfer are done in parallel, the time per iteration is

$$\max(t_{\text{arith}}/o, t_{\text{mem}}/o) = 1/\min(\text{frequency}, a \cdot \text{bandwidth})$$

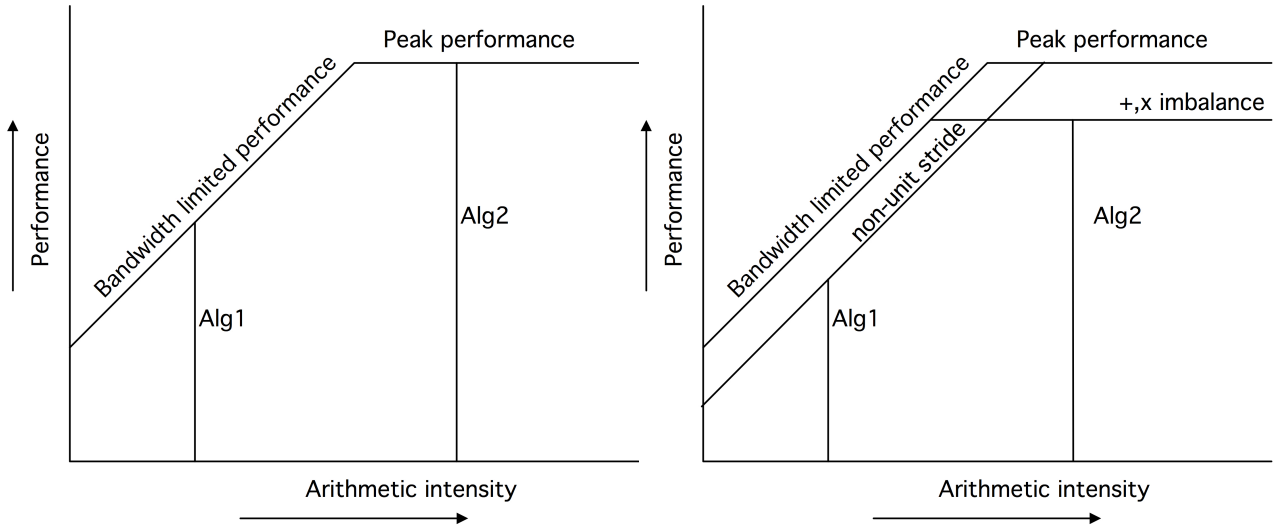
So the number of operations per second is $\min(\text{frequency}, a \cdot \text{bandwidth})$.

This piecewise linear function in a gives the *roofline model*.

Tip

See examples in [Eij10; Section 1.6.1].

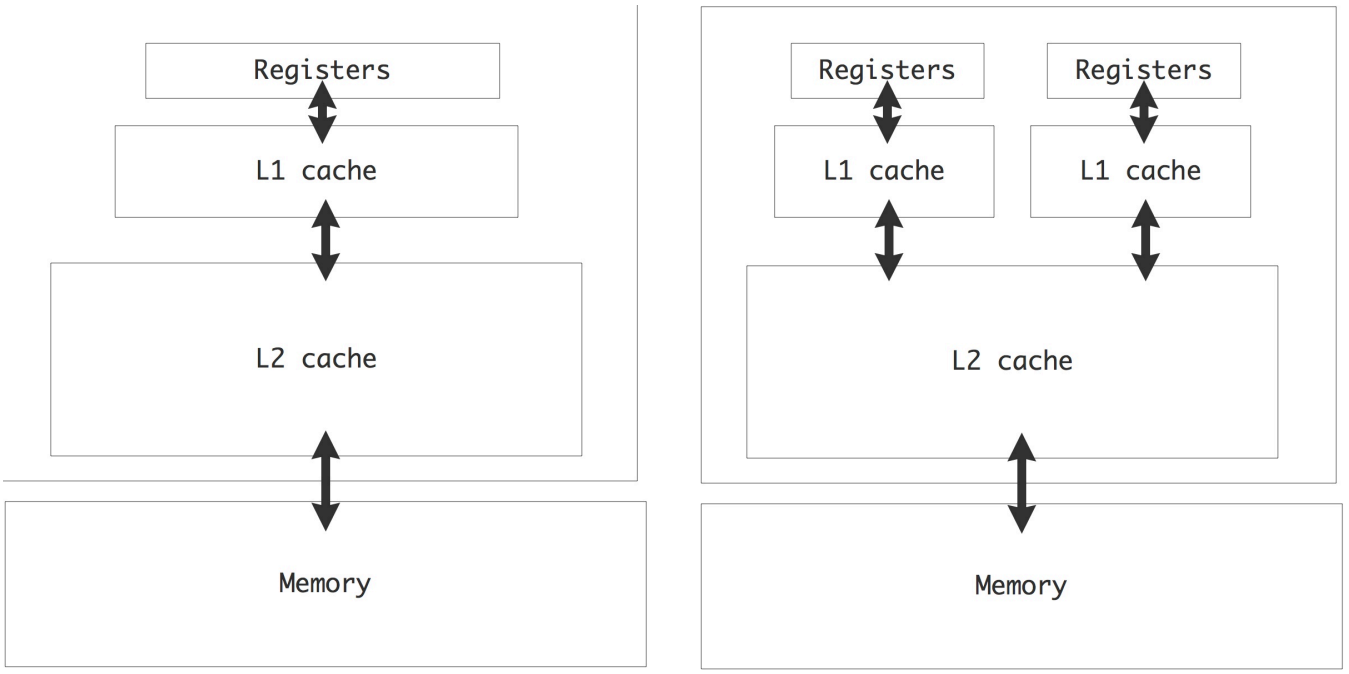
The roofline model



- *compute-bound* : For large arithmetic intensity (Alg2 in above picture), performance determined by processor characteristics
- *bandwidth-bound* : For low arithmetic intensity (Alg1 in above picture), performance determined by memory characteristics
- Bandwidth line may be be lowered by inefficient memory access (e.g., no locality)
- Peak performance line may be lowered by inefficient use of CPU (e.g., not using SIMD)

[Eij10; Figure 1.16]

Cache hierarchy for a multi-core CPU



Cache coherence : Update L1 cache when the corresponding memory is modified by another core.

[Eij10; Figure 1.13]

Parallel sum

```
#include <vector>
#include <stdint.h>
#include <omp.h>
#include <stdio.h>

extern "C" {
float sum(float *vec, int length, int num_threads, int verbose) {
  float total = 0;
  omp_set_dynamic(0); // Force the value `num_threads`
  omp_set_num_threads(num_threads);
  #pragma omp parallel
  {
    int thread_num = omp_get_thread_num();
    int stride = length / num_threads;
    int last = stride * (thread_num + 1);
    if (thread_num + 1 == num_threads)
      last = length;
    if (verbose >= 1)
      fprintf(stderr, "thread id : %d / %d %d:%d\n", thread_num, omp_get_num_thre
ads(), stride * thread_num, last - 1);
    #pragma omp simd
    for (int i = stride * thread_num; i < last; i++)
      total += vec[i];
  }
  return total;
}
}
```

32833.78f0

```
@btime c_sum($vec, num_threads = 1, verbose = 0)
```

```
2.733 μs (0 allocations: 0 bytes)
```

32833.77f0

```
@btime c_sum($vec; num_threads, verbose = 0)
```

```
2.164 μs (3 allocations: 80 bytes)
```

```
32833.77f0
```

```julia
@time c_sum(vec; num_threads, verbose = 1)
```

```
thread id : 0 / 2 0:32767
thread id : 1 / 2 32768:65535
  0.000041 seconds
```

```
vec =
▸[0.397108, 0.76754, 0.90571, 0.924596, 0.732376, 0.69903, 0.0244073, 0.254985, 0.999074, 0
```

```julia
vec = rand(Cfloat, 2^log_size)
```

```julia
c_sum(x::Vector{Cfloat}; num_threads = 1, verbose = 0) = ccall(("sum", sum_lib),
Cfloat, (Ptr{Cfloat}, Cint, Cint, Cint), x, length(x), num_threads, verbose);
```

Low level implementation using POSIX Threads (pthreads) covered in "LEPL1503 : Projet 3". We use the high level OpenMP library in this course.

log_size = 16

num_threads = 2

▸ **Can you spot the issue in the code ?**

Many processors

```
#include <omp.h>
#include <stdio.h>

extern "C" {
void sum_to(float *vec, int length, float *local_results, int num_threads, int ve
rbose) {
  omp_set_dynamic(0); // Force the value `num_threads`
  omp_set_num_threads(num_threads);
  #pragma omp parallel
  {
    int thread_num = omp_get_thread_num();
    int stride = length / num_threads;
    int last = stride * (thread_num + 1);
    if (thread_num + 1 == num_threads)
      last = length;
    if (verbose >= 1)
      fprintf(stderr, "thread id : %d / %d %d:%d\n", thread_num, omp_get_num_thre
ads(), stride * thread_num, last - 1);
    float no_false_sharing = 0;
    #pragma omp simd
    for (int i = stride * thread_num; i < last; i++)
      no_false_sharing += vec[i];
    local_results[thread_num] = no_false_sharing;
  }
}

float sum(float *vec, int length, int num_threads, int factor, int verbose) {
  float* buffers[2] = {new float[num_threads], new float[num_threads / factor]};
  sum_to(vec, length, buffers[0], num_threads, verbose);
  int prev = num_threads, cur;
  int buffer_idx = 0;
  for (cur = num_threads / factor; cur > 0; cur /= factor) {
    sum_to(buffers[buffer_idx % 2], prev, buffers[(buffer_idx + 1) % 2], cur, ver
bose);
    prev = cur;
    buffer_idx += 1;
  }
  if (prev == 1)
    return buffers[buffer_idx % 2][0];
  sum_to(buffers[buffer_idx % 2], prev, buffers[(buffer_idx + 1) % 2], 1, verbos
e);
  return buffers[(buffer_idx + 1) % 2][0];
}
}
```

Benchmark

If we have many processors, we may want to speed up the last part as well:

32833.78f0

```julia
@time many_sum(vec; base_num_threads, factor, verbose = 1)
```

```
thread id : 0 / 2 0:32767
thread id : 1 / 2 32768:65535
thread id : 0 / 1 0:1
  0.000078 seconds
```

32782.07f0

```julia
@btime c_sum($many_vec)
```

```
  2.737 μs (0 allocations: 0 bytes)
```

32782.07f0

```julia
@btime many_sum($many_vec; base_num_threads, factor)
```

```
  6.236 μs (3 allocations: 80 bytes)
```

many_vec =

▸ [0.232957, 0.110716, 0.918202, 0.741591, 0.970198, 0.643649, 0.915733, 0.817722, 0.167178

```julia
many_vec = rand(Cfloat, 2^many_log_size)
```

```julia
many_sum(x::Vector{Cfloat}; base_num_threads = 1, factor = 2, verbose = 0) =
ccall(("sum", many_sum_lib), Cfloat, (Ptr{Cfloat}, Cint, Cint, Cint, Cint), x,
length(x), base_num_threads, factor, verbose);
```

many_log_size = 16

base_num_threads = 2

factor = 2

Amdahl's law

Speed-up and efficency

Def: Speed-up

$$S_p = \frac{T_1}{T_p}$$

Def: Efficiency

$$E_p = \frac{S_p}{p}$$

Let T_p bet the time with p processes

- $E_p > 1$ → Unlikely
- $E_p = 1$ → Ideal
- $E_p < 1$ → Realistic

Amdahl's law

- F_s : Percentage of T_1 that is sequential
- $F_p = 1 - F_s$: Percentage of T_1 that is parallelizable

$$T_p = T_1 F_s + T_1 F_p / p$$

$$S_p = \frac{1}{F_s + F_p/p} \qquad E_p = \frac{1}{pF_s + F_p}$$

$$\lim_{p \to \infty} S_p = \frac{1}{F_s}$$

Application to parallel sum

The first `sum_to` takes n/p operations. Assuming `factor` is `2`, there is one operation for each of the $\log_2(p)$ subsequent `sum_to`.

$$
\begin{aligned}
T_1 &= n \\
T_p &= n/p + \log_2(p) \\
S_p &= \frac{1}{1/p + \log_2(p)/n} \qquad E_p = \frac{1}{1 + p\log_2(p)/n}
\end{aligned}
$$

▶ **How to get $1/F_s = \lim_{p\to\infty} S_p$?**
